Bat-borne Mycobacterium avium subsp. hominissuis (MAH) is the second most common cause of nontuberculous mycobacteria disease in humans following MAH in birds. These infections are underdiagnosed and rarely treated. We characterized a MAH strain from human specimens for use as a standard challenge strain to facilitate research on MAH. We cultured MAH CA12 from sputum from a 2-year-old boy in Asia and developed a minimal medium that supported its growth. We also examined the influence of growth factors on CA12. CA12 grew in the presence of 0.1 % tyloxapol (Tween 80), but not in the presence of surfactant alone. Sulfhydryl (-SH) content in the bacterium increased 5-10 times in 10 days in the presence of 1 % sulfhydryl agents, but not in the presence of 10 % bovine serum albumin (BSA). Fatty acid analysis of strain CA12 revealed that C16:0, C18:0 and C24:0 were major components. Tetradecanoic acid was found in the cell wall of the CA12 strain. Carbon isotope ratios of the strain and the amino acids in the cell wall were similar to those in the bovine muscle in which it was obtained. We conclude that this strain, CA12, is useful as a reference strain for clinical trials.Why we made this change Visitors are allowed 3 free articles per month (without a subscription), and private browsing prevents us from counting how many stories you've read.
