The success in nanoscience and nanotechnology will largely be dictated by the ability to obtain accurate information on the nanoscale, which will be critical in the design and development of new materials and devices for nanotechnology. Scanning probe microscopy (SPM), in particular atomic force microscopy (AFM), offers the finest nanoscale details with submolecular spatial resolution. The crucial aspect of AFM is its unique imaging mode, that is the interplay between tip and sample. On the one hand, it is affected by the interface between the tip and the sample. On the other, it is highly sensitive to surface and subsurface phenomena. This can be exploited in different ways to detect nanoscale surface properties of a sample, as well as to follow changes of the tip-sample interaction during scanning to obtain 3D information. The most common types of interactions are dynamic force microscopy (DFM) and tapping/tunnelling/non-contact mode (TnCM) AFM. The parameters that affect the interaction are the repulsive or attractive forces between the tip and sample, the tip geometry, the tip material and the sample material. In this review, we provide a comprehensive introduction into the nanosc f988f36e3a
